

# Custom Taxonomies

You can create custom taxonomies to help organise and classify content in the Juicebox theme. To register a custom taxonomy, the recommended approach is to create a new PHP file within the `src/JuiceBox/Taxonomy` folder. The file should define a new class that extends from the `CustomTaxonomy` abstract class.

The naming convention for the class should be singular and match the taxonomy name, for example, if you were creating a custom taxonomy for products, you might call the class `Product`. The `CustomTaxonomy` abstract class provides some basic functionality, such as setting default labels and enabling the taxonomy to be used with the WordPress REST API.

Within the class, you can customize the behaviour of the taxonomy by overriding some of the methods defined in the abstract class. For example, you might want to change the slug for the taxonomy or modify the way the taxonomy is displayed in the WordPress admin. Once you have defined your custom taxonomy, it will be automatically registered with WordPress when the theme is activated.
