

Timber/Twig Templates

The Juicebox WordPress base theme uses the Timber library, which is a popular WordPress package that allows developers to use the Twig templating engine with WordPress.

Twig is a modern and powerful templating engine that makes it easier to create and maintain complex HTML/CSS/JS code. It provides several useful features, such as template inheritance, macros, and filters, which can help reduce the amount of code needed to create and maintain WordPress themes.

It is highly recommended to familiarize yourself with both Timber and Twig documentation when working with the Juicebox theme. By learning how they work, you can take full advantage of their features and create more efficient and modular code. Some useful resources for learning about Timber and Twig include:

- The Timber documentation: <https://timber.github.io/docs/>
- The Twig documentation: <https://twig.symfony.com/doc/2.x/>
- Twig for WordPress: <https://twiganything.com/twig-for-wordpress/>

In essence, the template files in the Juicebox theme are designed to simply pass data to the Timber render function, which then renders the templates using Twig. By understanding how Timber and Twig work, you can better understand how to structure your templates and utilize their advanced features.
