# Custom Post Types

You can define your own custom post types to create specialised content types that are unique to the website. To register a custom post type in the Juicebox theme, you can create a new class in the folder `src/JuiceBox/PostType` using the `Example.php` file as a starting point. The name of the class should be singular and match the singular form of the custom post type.

For instance, if you're creating a custom post type for books, you would name the class `Book`. Additionally, the name of the custom post type should also be singular. Once you create your custom post-type class, it should extend from the `CustomPostType` abstract class.

By default, custom post types are automatically registered when you create a new class in the `PostType` folder. However, if you need to customize the registration process, you can modify the `register()` function in the `CustomPostType` abstract class to include additional options or post-type arguments. With this setup, you can quickly and easily create and manage custom post types for your WordPress website.
